You vs flu season

TRUST FLUZONE QUADRIVALENT VACCINE—
THE FIRST AND ONLY 4-STRAIN INFLUENZA
VACCINE APPROVED FOR PATIENTS AS YOUNG
AS 6 MONTHS OF AGE.¹

Please click here for Important Safety Information.
While seasonal flu outbreaks can happen as early as October, flu activity usually peaks between December and February—and can last as late as May. The influenza B strain puts your pediatric patients at greater risk. Over multiple recent flu seasons, more than 1 in 3 flu-related deaths in children were directly due to influenza B. Every year, an average of 20,000 children younger than 5 years of age are hospitalized due to complications from flu. Children with chronic health problems like asthma and diabetes are at even greater risk of complications. Many pediatric offices stop offering flu vaccine after October. A national flu immunization survey of 605 parents found that fewer pediatric offices offered flu immunization as the 2014-2015 flu season progressed. The Centers for Disease Control and Prevention (CDC) recommends that health care professionals continue vaccinating throughout the entire flu season. While seasonal flu outbreaks can happen as early as October, flu activity usually peaks between December and February—and can last as late as May.

IMPORTANT SAFETY INFORMATION

INDICATION
Fluzone Quadrivalent vaccine is indicated for active immunization for the prevention of influenza disease caused by influenza A subtype viruses and type B viruses contained in the vaccine.

Fluzone Quadrivalent vaccine is approved for use in persons 6 months of age and older.

SAFETY INFORMATION
The most common local and systemic adverse reactions to Fluzone Quadrivalent vaccine include pain (tenderness in young children), erythema, and swelling at the injection site; myalgia, malaise, headache, and fever (irritability, abnormal crying, drowsiness, appetite loss, and vomiting in young children). Other adverse reactions may occur. Fluzone Quadrivalent vaccine should not be administered to anyone with a known hypersensitivity (eg, anaphylaxis) to any vaccine component, including egg protein or thimerosal (the multidose vial is the only presentation containing thimerosal), or to a previous dose of any influenza vaccine.

If Guillain-Barré syndrome has occurred within 6 weeks following previous influenza vaccination, the decision to give Fluzone Quadrivalent vaccine should be based on careful consideration of the potential benefits and risks. Vaccination with Fluzone Quadrivalent vaccine may not protect all individuals.

Before administering Fluzone Quadrivalent vaccine, please click here for full Prescribing Information.
